ABSTRACT

Introduction: Polycystic ovary syndrome (PCOS) is a complex disease having genetic, immunologic, and environmental components, and candidate genes on innate immunity have been hypothesized to be involved in its etiology. We examined the possible association of CD14 and toll-like receptor 4 (TLR4) polymorphisms with PCOS.

Materials and methods: A total of 219 women with PCOS and 272 healthy women were recruited in the study. Their samples were genotyped for the polymorphism of CD14 and TLR4 genes.

Results: The distributions of genotypes of both polymorphisms were found to be significant in women with PCOS compared with controls. The distributions of alleles were also found to be predominant in PCOS compared with controls.

Conclusion: Polymorphisms in CD14-159C>T and TLR4-299A>G significantly increased susceptibility to PCOS. Further studies with larger sample sizes are warranted to confirm these findings.

Keywords: CD14, Polycystic ovary syndrome, Polymorphisms, Toll-like receptor 4.

INTRODUCTION

Polycystic ovary syndrome affects about 1 in 10 women of reproductive age and is the most common endocrine condition in this group. It is a heterogeneous disease characterized by oligomenorrhea due to increased ovarian and adrenal androgen secretion, and hyperandrogenic symptoms such as hirsutism, acne, and/or alopecia. Multiple endocrinological, metabolic abnormalities and anovulation are associated with PCOS. Around 80% of women with PCOS have irregular menstrual cycles; many are anovulatory. Some patients are managing to conceive effectively after treatment, but there is a high risk of complications during pregnancy as well as neonatal complications. This disorder is also associated with an increased risk of hyperinsulinemia, insulin resistance, type II diabetes mellitus, dyslipidemia, and cardiovascular diseases.

The etiology of PCOS is not yet clear. However, environmental, genetic, immunological, and biochemical factors are concerned with the etiopathogenesis of PCOS. Several candidate genes have been proposed as significant contributors to PCOS, but none have yet achieved acceptance as major cause. The PCOS is related with chronic inflammation, and genes related to innate immunity may contribute to its pathogenesis. To the best of our knowledge, no studies have examined the possible association of genetic variants in the genes encoding TLRs and CD14 with PCOS from India.

Several studies have shown that a polymorphism in the CD14 proximal promoter, −159C/T (rs2569190), might act together with environmental factors in the progress of disease. Previous studies have investigated whether the −159C/T polymorphism in the CD14 gene is associated with different disease risks and the results have been contradictory and uncertain. The CD14 and TLR4 are interlinked components with clearly defined roles in immunologic and inflammatory pathways. The TLR4 is one of the important signaling receptors of innate immunity. It determines the presence of bacterial lipopolysaccharide (LPS) associated with CD14 or MD-2 and initiates a proinflammatory signaling cascade. The classical mechanism by which LPS-induced TLR4 signaling includes activation of mitogen-activated protein kinases and nuclear factor κB results in secretion of proinflammatory cytokines such as tumor necrosis factor-α, interleukin-1β (IL-1β), IL-6, and others. In dendritic cells, CD14-dependent endocytosis pathway is upregulated upon exposure to inflammatory mediators. The aim of our study was to investigate the impact of
gene (CD14 and TLR4) polymorphisms involved in the innate immune system on PCOS.

MATERIALS AND METHODS

Study Population

A total of 219 patients and 272 controls were recruited from Owaisi Hospital and Research Centre, Hyderabad, India, in the present study. Patients were recruited based on Rotterdam criteria according to which a woman is said to have PCOS if she has any two features such as polycystic ovaries on ultrasound scan and menstrual irregularities. Ultrasound-scanned normal fertile women with no menstrual dysfunction or histories of infertility were recruited as controls. Written consent was taken from all subjects. The study was approved by the Institutional Review Board, Deccan College of Medical Sciences. Detailed information on clinical, anthropometric measures and diet was recorded through pro forma. Our sample size of 491 (219 patients + 272 controls) is large enough and exceeds the estimated number of samples (~200 cases + controls) required to obtain a 90% statistical power.

Molecular Analysis

Two milliliter of peripheral blood sample was collected from each participant. Deoxyribonucleic acid was extracted from peripheral blood samples and genotyping was done for CD14 and TLR4 genes. Genotyping of CD14 –159C>T polymorphisms was performed using the tetra-primer amplification refractory mutation system–polymerase chain reaction as described previously with minor modifications (annealing temperature 59°C). Polymorphism in the TLR4 (299A>G) was performed by allele-specific amplification as described previously. All amplifications were repeated twice and were analyzed using agarose gel electrophoresis system.

Statistical Analysis

The genotypic distribution of CD14 and TLR4 gene was performed using χ² test. Distribution of genotypes and alleles between PCOS and control groups was tested using Fisher’s exact test. Since differences between conditional logistical regression and unconditional logistical regression were small, unconditional logistical regression was used to estimate odds ratio (OR) and 95% confidence interval (CI). The above statistical analysis was performed using GraphPad Prism version 5.0 (GraphPad Software, Inc., San Diego, California, USA).

RESULTS

The “T” allele was found to be in higher frequency in PCOS compared with controls (0.37 vs 0.16, respectively; Table 1).

Heterozygote CT was found to be predominant in PCOS (0.68) when compared with controls (0.29; Table 2).

The CT genotype was found to be predominant in PCOS with 5.53-fold increased risk to PCOS when compared with wild-type genotype (CC) (OR 5.53, 95% CI 3.73–8.20, p < 0.0001). Homozygous variant was also observed to be associated with PCOS (OR 5.17, 95% CI 1.46–18.23, p < 0.0001). Dominant model (CT + TT) was also found to be associated with high risk to PCOS (OR 5.51, 95% CI 3.74–8.14, p < 0.0001; Table 3). Overdominant model CT (compared with CC + TT genotype) genotype

| Table 1: CD14 allele frequency distribution in controls and PCOS |
|-----------------------------|-----------------------------|-----------------------------|
| Allele | Control Number | Control Frequency | Patients Number | Patients Frequency |
| C     | 457            | 0.84             | 276             | 0.63             |
| T     | 87             | 0.16             | 162             | 0.37             |

| Table 2: CD14 genotypic frequency distribution in controls and PCOS |
|-----------------------------|-----------------------------|-----------------------------|
| Genotype | Control Number | Control Frequency | Patients Number | Patients Frequency |
| C/C     | 189 (69.5%)    | 0.69             | 64              | 0.29             |
| C/T     | 79 (29%)       | 0.29             | 148             | 0.68             |
| T/T     | 4 (1.5%)       | 0.01             | 7               | 0.03             |

| Table 3: Odds risk estimation of the CD14 genotype in PCOS compared with controls |
|-----------------------------------------------|-----------------------------|-----------------------------|
| Model | Genotype | Control | Patients | OR (95% CI) | p-value |
| Codominant | C/C     | 189 (69.5%) | 64 (29.2%) | 1.00 | <0.0001 |
|          | C/T     | 79 (29%)    | 148 (67.6%) | 5.53 (3.73–8.20) | |
|          | T/T     | 4 (1.5%)    | 7 (3.2%)    | 5.17 (1.46–18.23) | |
| Dominant | C/C     | 189 (69.5%) | 64 (29.2%) | 1.00 | <0.0001 |
|          | C/T–T/T | 83 (30.5%)  | 155 (70.8%) | 5.51 (3.74–8.14) | |
| Recessive | C/C–C/T | 268 (98.5%) | 212 (96.8%) | 1.00 | 0.2 |
|          | T/T     | 4 (1.5%)    | 7 (3.2%)    | 2.21 (0.64–7.66) | |
| Overdominant | C/C–T/T | 193 (71%)  | 71 (32.4%) | 1.00 | <0.0001 |
|          | C/T     | 79 (29%)    | 148 (67.6%) | 5.09 (3.46–7.49) | |
was also observed to be associated with high risk to PCOS (OR 5.09, 95% CI 3.46–7.49, p < 0.0001; Table 3).

The “G” allele was found to be in higher frequency in PCOS compared with controls (0.39 vs 0.19, respectively; Table 4).

Heterozygote CT was found to be predominant in PCOS (0.68) when compared with controls (0.35; Table 5). The AG genotype was found to be predominant in PCOS with 4.68-fold increased risk to PCOS when compared with wild-type genotype (CC; OR 4.68, 95% CI 3.16–6.93, p < 0.0001) (Table 6). Homozygous variant was also observed to be associated with PCOS (OR 5.17, 95% CI 1.46–18.23, p < 0.0001). Dominant model (CT + TT) was also found to be associated with high risk to PCOS when compared with controls. The present study has shown the “T” allele of CD14 (−159C>T) was found to be in higher frequency in PCOS compared with controls (0.37 vs 0.16 respectively).

Härtel et al17 demonstrated genotypic frequencies for CD14 (−159C>T) of infants, and no significant differences were noted between preterm very low birth weight and term infants. Our study has shown that heterozygote CT of CD14 was found to be predominant in PCOS (0.68) when compared with controls (0.29). The result of the current study showed that CT genotype was found to be significant in PCOS when compared with controls. Homozygous variant was also observed to be associated with PCOS (OR 5.86, 95% CI 1.93–17.86, p < 0.0001). Dominant model (CT + TT) was also found to be associated with high risk to PCOS when compared with controls. The AG genotype was found to be predominant in PCOS with 4.68-fold increased risk to PCOS when compared with controls. Heterozygote CT was found to be predominant in PCOS (0.68) when compared with controls (0.35).

**DISCUSSION**

The recognition of genes underlying complex traits is an exigent task, and there are an inadequate number of established genes that influence human complex diseases.16 In particular, a small number of genes concerned with complex diseases associated with immune response, such as inflammatory diseases and infectious diseases, have been identified.16 In 2015, large-scale genetic and functional studies brought us closer to understanding the underlying etiology of PCOS. In this study, we have analyzed two innate immune gene polymorphisms (CD14 and TLR4) among women with PCOS and in healthy controls and experienced their association with PCOS.

The present study has shown the “T” allele of CD14 (−159C>T) was found to be in higher frequency in PCOS compared with controls (0.37 vs 0.16 respectively). Härtel et al17 demonstrated genotypic frequencies for CD14 (−159C>T) of infants, and no significant differences were noted between preterm very low birth weight and term infants. Our study has shown that heterozygote CT of CD14 was found to be predominant in PCOS (0.68) when compared with controls (0.29). The result of the current study showed that CT genotype was found to be significant in PCOS when compared with controls. Homozygous variant was also observed to be associated with PCOS (OR 5.17, 95% CI 1.46–18.23, p < 0.0001). Dominant model (CT + TT) was also found to be associated with high risk to PCOS when compared with controls. The AG genotype was found to be predominant in PCOS with 4.68-fold increased risk to PCOS when compared with controls. Heterozygote CT was found to be predominant in PCOS (0.68) when compared with controls (0.35).
Genetic variations of the CD14 and TLR4 gene may have a distinct role in certain disease states. However, some studies suggest that synonymous single nucleotide polymorphisms (SNPs) might be able to change the resulting phenotypes, for example, abnormal kinetics of protein translation that would result in the folding of the polypeptide chain in different final conformations and, consequently, different cellular functions.  

In conclusion, our data suggest that polymorphisms of the innate immune genes (CD14 and TLR4) have a higher impact on PCOS. Because these genes are interlinked with each other, further studies are required to gain insight on how SNPs in each of the genes alter the protein structure and interaction, resulting in perturbation of the delicate immunologic balance in PCOS.
