Hypocalcemia and Vitamin D Deficiency in Patients Post-bariatric Surgery: A Systematic Review

Pallikonda S Madhulika, Juan González-Tova

ABSTRACT

Introduction: Bariatric surgery is viewed as the best tool for the control and treatment of severe obesity; however, postsurgery, they have a greater risk of developing nutritional deficiencies as this procedure hinders the absorption of most of the nutrients.

Objective: To evaluate the effect of vitamin D insufficiency and that of calcium in bone in patients after Roux-en-Y gastric bypass (RYGB), and the mode of administration of calcium, its dosage, and efficacy.

Materials and methods: A precise survey was performed with articles identified that are associated with the subject of interest. Articles from 10 years back were looked up in PubMed, the US National Library of Medicine, the National Institutes of Health, Medline, Lilacs, Scielo, and Cochrane utilizing the headings "bariatric surgery," "bone," "obesity," "vitamin D," "calcium," and "absorption."

Results: Five articles were incorporated into this survey that have analyzed the facts that bariatric surgery can cause wholesome inadequacies of nutrition and poor assimilation of fats and fat-dissolvable vitamins and micronutrients, e.g., calcium.

Conclusion: Patients submitted to RYGB should make use of multivitamins and minerals, especially vitamin D and calcium to prevent bone fractures. Monitoring, treatment, and control of risk factors are essential to prevent complications after this operation.

Keywords: Bariatric surgery, Calcium deficiency, Vitamin D deficiency.

INTRODUCTION

Since the advent of bariatric surgery, numerous surgical techniques for the treatment of obesity have been proposed and further improvised over the decades. The RYGB is an operation, i.e., viewed as a gold standard of treatment for extreme obesity in light of the fact that it results in fewer serious side effects and complications than conventional malabsorption techniques, e.g., jejunoileal bypass. The malabsorption methodologies have been perceived as a risk factor for diseases of bone because of the resulting alteration of calcium metabolism and decreased absorption. Some studies explored these deranged levels of calcium tentatively in patients with jejunoileal bypass, and demonstrated that assimilation diminishes by half after surgery. Insufficient calcium intake is common after gastric bypass, further increasing the bone loss. Comprehending the postoperative RYGB, diminishing of calcium absorption and supplements, and exploring the dosages, modes of administration, and the duration of medication treatment and its impacts on bone were the sole objectives of this review.

MATERIALS AND METHODS

The population, intervention, comparison, and outcome (PICO) strategy was adopted to expound the response to the question, "How is bone lost in patients who experience bariatric surgery and what supplements help to diminish this loss?" Obese patients who had bone loss and additionally BMI from 35 to 39.9 kg/m² with comorbidities and ≥40 kg/m² (population); patients submitted to RYGB by laparoscopy or laparotomy (intervention); eutrophic patients with BMI of 18.5 to 24.9 kg/m² (comparison); patients with insufficiency of vitamin D and calcium and conceivable nearness of fractures (outcome) were selected.

Qualification Criteria for Study Consideration

Inclusion Criteria

All studies; patients of age 15 to 70 years; BMI from 35 to 39.9 kg/m² with comorbidities and ≥40 kg/m²; ≥3 months postsurgery; and laparoscopic or laparotomic RYGB.

Exclusion Criteria

Pregnant women or, women in lactation; smoking or previous smoker; people treated with bisphosphonates; and animals.
Hypocalcemia and Vitamin D Deficiency in Patients Post-bariatric Surgery

Types of Outcome

Essential outcome was engaged in vitamin D and calcium inadequacy; nonetheless, conceivable bone fractures were investigated after bariatric surgery. As auxiliary outcomes, connection between the kind of supplement administration and the body’s capability in engrossing the administered medication was looked at; and the dosages and their consequences for the maintenance or recuperation of bone resorption after bariatric surgery were observed.

Search Strategy

PubMed/Medline, Lilacs, Scielo, and Cochrane were utilized with the headings “bariatric surgery,” “bone,” “stoutness,” “vitamin D,” “calcium,” “AND” “assimilation.” Following the collection of data, examination of the title, perusing of the theoretical abstracts, the complete perusing of the articles was made.

RESULTS

Table 1 shows the methodological characteristics of the selected studies. Of the five articles, three corresponded to prospective cohort studies;18-22 two used the laparoscopic approach and one enrolled only women; there was one case report and one case series. All assessed the nutritional status and bone fractures, routes of administration, as well as the respective dosage of vitamin D and calcium; one article evaluated the parathyroid hormone and its influence on bone reabsorption in RYGB.

DISCUSSION

The results of this systematic review are based on five publications. The research did not identify bone fractures in patients undergoing bariatric surgery; nonetheless, there appeared high inadequacies in vitamin D and calcium in the bones. The studies demonstrated the diverse ways of administration and the results, noting the different answers regarding insufficiencies that emerge in the bone tissue because of dose and adequacy, as indicated by the route of administration. After bariatric surgery, all investigations pronounced outcomes with deficiency in the bones of patients, paying little heed to the kind of bariatric surgery. All studies specified administration of vitamin D and calcium by means of tablets or infusions in various doses.

None of them exhibited complete loss of bone calcium, yet demonstrated a critical distinction in bone resorption, fundamentally by parathyroid hormone. Parathyroid hormone increases the movement of osteoclasts, prompting the devastation of the cortical bone, indicating a likewise marked inadequacy of vitamin D.15,19 finally debilitating the bones and then leading to the likelihood of fractures in the postoperative period. Avgerinos et al21 in their essential prospective cohort in people of the two sexual orientations for a period of 2 years have demonstrated the significance of vitamin D supplementation to prevent the decline of calcium in the bones.

Research investigated women in pre- and postmenopausal stages demonstrating that there was no critical difference between them in calcium absorption inadequacy and even the differences in relationship to the sort of surgery were not present.17,18,23

As per this review, the sort of administration and dosage had no relationship or significance over time on drug treatment. Nonetheless, no direct connection to the postoperative bone loss was demonstrated. Vasconcelos et al18 considered the calcium intake in the eating routine of 600 mg and supplemented with 200 mg as tablet form during the 22 months in the operated group. Although the intake was fundamentally higher than in the nonoperated group, it was still lower than the prescribed levels for these patients, which ought to be between 1,000 and 1,800 mg/day.24,26

Intake of vitamin D (500 IU) was likewise beneath the prescribed levels. It can be deduced from the postoperative vitamin supplementation that it ought not just comprise multivitamins, since most do not contain the calcium and vitamin D required and prescribed to be taken each day. The above changes may increase the postoperative and preoperative screening; care ought to be taken to prevent the changes in bone metabolism. Reasonable supplementation of vitamins and minerals is basic to avoid or limit bone metabolic intricacies that can happen after RYGB.27

Another important factor apart from vitamin D supplementation and calcium that may influence bone change in these patients is age, other than the differences in between women in premenopausal and postmenopausal women that need particular approach. There are different elements that can impact straightforwardly and add to bone resorption, which include lack of vitamin D, deficient calcium intake, and secondary hyperparathyroidism, present sometimes in the obese. The parathyroid hormone additionally increases the activity of osteoclasts, prompting bone cortical destruction to make up for the abatement of serum calcium.10

In connection with bone density and fracture prevalence, no significant differences in the studies were found. It is conceivable that the generally short follow-up contributed to the lack of identification of bone fracture. Future research is needed to better elucidate the bone complications in these patients.

RYGBL: Roux-en-Y gastric bypass laparoscopy
CONCLUSION

Patients undergoing RYGB should make use of multivitamins and minerals, especially calcium and vitamin D to prevent bone fractures. Monitoring, treatment, and control of risk factors are essential to prevent these complications after the surgery.
