A Clinical Study on Eclampsia in a Referral Hospital

Parneet Kaur

ABSTRACT

Objective: To analyze the cases of eclampsia in a referral hospital, like GGS Medical College, Faridkot, with special focus on booked/unbooked/referred, age, parity and antenatal care. Also fetomaternal outcome was seen in all the cases.

Materials and methods: All the cases of eclampsia referred from nearby rural areas, civil hospitals and CHCs sent here for specialist care were studied in this 2 years study from July 2003 to June 2005.

Results and conclusions: A total of 50 cases of eclampsia were admitted. The incidence came out to be 7.4%. Ninety-eight percent of cases were unbooked. Majority of the cases belonged to 21 to 30 years age group. Fifty-six percent of the cases were primigravida. Eighty-eight percent had no antenatal check-up at all. Thirty percent of babies were still born and 12% had early neonatal death. There were three maternal deaths. Antepartum eclampsia was most common seen in 68% of cases. We concluded that there is lack of antenatal care in rural areas and urban slums and this needs to be addressed to prevent this serious complication of pregnancy. Moreover, personnel at district hospitals and CHCs should be capable of administering magnesium sulfate, the anticonvulsant as none of the patient threw a fit after loading dose of magnesium sulfate.

Keywords: Eclampsia, Magnesium sulfate, Referral hospital.

INTRODUCTION

Though by the end of twentieth century, eclampsia has become almost unknown to obstetricians in the developed countries, it still remains an important factor of maternal and perinatal morbidity and mortality in the developing countries, like India. It is estimated that every year eclampsia is associated with 50,000 maternal deaths worldwide most of which occur in developing countries.1 The incidence of eclampsia is still high in referral hospitals though it is a preventable complication of pregnancy.2 Without a doubt proper antenatal care is the most important part of prevention.

MATERIALS AND METHODS

GGS Medical College is a referral Hospital. All cases from nearby rural areas, CHCs, civil hospitals and private nursing homes are sent here for specialist care. In this 2 years study, from July 2003 to June 2005, a total of 50 cases of eclampsia were admitted. All the cases were analyzed with special focus on booked/unbooked/referred, age, parity and antenatal care. Also fetomaternal outcome was seen in all the cases. On admission, all cases were thoroughly examined and put on treatment.

- All the cases were put on Pritchard’s regime giving magnesium sulfate 4 gm I/V bolus dose and 5 gm I/M in each buttock followed by 5 gm I/M in alternate buttock 4 hourly
- S/L Nifedipine was given for control of BP
- Supportive therapy in form of I/V line, suction SOS, continuous catheterization, oxygen inhalation and mouth gag, etc. was given
- After stabilization of patient, obstetrical management was carried out.

OBSERVATIONS

The incidence of eclampsia came out to be 7.4%. Only one case in the study was booked (2%). Rest all cases were unbooked (36%) or referred (62%) from nearby CHCs, civil hospitals and private nursing homes (Table 1).

Majority of the cases had no antenatal check-up (88%) and were illiterate (96%). A large number of cases belonged to rural background (80%).

Maximum number of cases was between age groups of 21 and 30 years (62%). Twenty-six percent were below 20 years of age and 12% above 30 years.

Highest number of females was primigravida in this study (Table 2).

Antepartum eclampsia was the commonest variety (68%), followed by postpartum eclampsia (20%) and intrapartum eclampsia (12%) (Table 3).

Seventy-six percent of the subjects had vaginal delivery, 4% forcesps delivery and 20% underwent lower segment cesarean section (LSCS).

In our study, none of the patient threw a fit after initiation of magnesium sulfate therapy which is a very important observation.

Maximum number of patients presented in third trimester of pregnancy (96%) except 4% who had gestation of less than 28 weeks.

Maternal complications occurred in the form of DIC, postpartum pyrexia, oliguria and postpartum hemorrhage (PPH), etc. (Table 4). The complication rate came out to be 38%.

Maternal mortality in present study came out to be 6% (Table 5).

There were 56% alive births, 30% still-births and 12% early neonatal deaths (Table 6).

Sixty-two percent of the cases were referred from nearby civil hospitals, CHCs and private nursing homes in present study which is nearly same as reported by Shaheen B et al (66.2%).3

Large number of cases in our study was from rural background, illiterate, unbooked with no antenatal check-up. Similar findings were reported by Samal S et al, Khanum M et al and Chandra and Bhardwaj.4-6

Majority of the cases in present study were primigravidas. Sheraz S et al (69.1%), Datta MR et al (66.0%) and Shaheen B et al (69%) also reported maximum occurrence of eclampsia in primis.5,7,8

Maximum number of cases were between 21 and 30 years of age which is comparable to Sarma HK (71.79%) and Sheraz S et al (78.2%).7,9 In our study, prevalence of antepartum eclampsia came out to be highest which is comparable to the studies of Sarma HK (69.23%), Sheraz S et al (67.3%) and Shaheen B et al (62%).3,7,9

Most of our subjects presented with fits at term pregnancy (72%). Similar findings were reported by Chourshay P.10

Maternal mortality of 6% in present study is comparable to that of Sheraz S et al (3.6%),6 Gaddi and Somegewoda (5.4%)11 but less as reported by Nobis PN (11.54%).12 Maternal mortality was high but comparable to that reported by Nobis PN (42.96%).12 Others have reported less maternal morbidity. Perinatal mortality in this study came out to be 44% which is quite high but also reported by Gaddi, Somegewoda (39.3%) and Khanum M et al (38%)5,11

In our study, none of the patient threw another fit after receiving loading dose of magnesium sulfate. Same findings were seen by Samal S et al4 where as some reported 2% recurrence rate.7

CONCLUSION

We concluded that there is lack of antenatal care in rural areas and urban slums and this needs to be addressed to prevent this serious complication of pregnancy. The personnel at district hospitals and CHCs should be capable of administering magnesium sulfate. Eclampsia is a largely preventable complication of pregnancy provided the pregnant women get proper health education and regular antenatal care. Toward this goal, early antenatal booking, careful and regular follow-up, knowledge of associated risk factors and an effort to detect this condition early are essential.

As it is associated are high maternal morbidity and mortality and poor perinatal outcome, so proper management of PIH and timely referral to higher center is important step. The unbooked cases going directly to community centers, civil hospital, and private doctors should be referred after giving preliminary treatment in form of magnesium sulfate, the anticonvulsant as delay in start of treatment means more complication rate.
