INTRODUCTION

The introduction of laparoscopic cholecystectomy has increased bile duct injuries by three to four folds.\textsuperscript{1,2} Bile duct injury can lead to bile leakage, peritonitis, stricture formation, cholangitis, jaundice, chronic liver disease and septicemia. These injuries are frequently amenable to delayed recognition and difficult reoperations due to inflammation, infection and malnutrition.\textsuperscript{3} A number of techniques have been devised to prevent such injuries and among these On-table cholangiography (OTC) is widely practiced. On-table cholangiography (OTC) was first recommended by Mirizzi\textsuperscript{4} in 1931 on the basis of high incidence of common bile duct stones and thus reducing the incidence of unnecessary CBD exploration from 66\% to < 5\%.\textsuperscript{5} In cholecystectomy, the routine use of OTC is controversial as it is useful to map the anatomy of the biliary tree but on the other hand it increases the operation time, cost and unnecessary CBD exploration due to poor quality images and false-negative and false-positive results. The debate becomes further complicated with the advent of laparoscopic cholecystectomy which demands additional technical skills for OTC.\textsuperscript{6} Numerous studies have shown that Laparoscopic cholecystectomy was performed safely with minimal use of OTC.\textsuperscript{7,8} While others insist the routine use of OTC during laparoscopic cholecystectomy to minimize the CBD injuries.\textsuperscript{9-11}
In our setup, On-table cholangiography is not performed routinely while doing laparoscopic cholecystectomy. It is mainly due to technical difficulty and nonavailability of the equipment in most hospitals. In this study, we report the outcome of a series of patients undergone LC without On-table cholangiography.

PATIENTS AND METHODS

This study was carried out in surgical “D” ward Khyber Teaching Hospital, Peshawar from January 2005 to December 2008. A total of 760 patients were included in this study. Patients of known gallstone disease without clinically and radiological proven complications (obstructive jaundice) were subjected to laparoscopic cholecystectomy. Patients were admitted through outpatient or emergency department. After proper history and examination the gallstone diseases was diagnosed by ultrasonography and CT-scan where needed. Patients with complications like obstructive jaundice or gallbladder mass were excluded from the study. All patients were operated as elective cases with laparoscopic procedure. Three ports laparoscopic cholecystectomy was performed in majority of the cases while four ports technique was adopted in difficult cases. Meticulous concentration was adopted for hepatobiliary anomalies. On-table cholangiography was performed in none of the cases. At the completion of procedure biliary tracts were examined carefully for evidence of evident or potential damage. They were observed for a day or two and then were discharged home. They were advised to attend the follow-up clinics at four to six weeks interval. During postoperative course and follow ups, they were looked for evidence of bile duct injury (peritonitis, biliary leakage through drain or biliary fistula). Thus detected cases of bile duct injury were admitted for further work up. The data were entered into a proforma and was analyzed and results were drawn at the completion of study.

RESULTS

Out of the total 760 cases that underwent laparoscopic cholecystectomy bile duct injury was observed in 7 (0.92%) seven cases (Table 1).

Partial Injury to CHD

There were 2 (0.26%) cases of partial injury to the common bile duct. One case was that of the “Mirizzi syndrome”. The opening between the Hartman’s pouch and CHD (common hepatic duct) became evident during dissection. Hence immediate laparotomy was done and T-tube placed. In the second case, a small spurt occurred from a vessel running over the CHD during dissection of dense adhesions in Calot’s triangle, hence diathermy was used to coagulate the bleeder. Nothing happened during the operation. The patient recovered well and was discharged home. However, the patient returned with biliary peritonitis after one week, ERCP confirmed the leak in CHD. Laparotomy showed a hole at the site where diathermy was used, a T-tube was placed.

Partial Injury to CBD

In 2 (0.26%) patients, the partial injury to CBD occurred due to tenting and both these injuries were detected peroperatively. The problem was rectified by conversion to open surgery and insertion of T-tube.

Complete Transaction of CBD

This occurred in 2 (0.26%) patients. In one, who had a very small gallbladder (hardly 2 cm), that was buried in the liver near porta hepatis. Besides the entire gallbladder was occupied by a large stone. Thus CBD was mistaken for cystic duct, clipped and divided. The gallbladder which was densely adherent with the under surface of liver and was separated by blunt and sharp dissection using scissors and diathermy hook, and removed. Drain was placed but next...

day it showed 400 cc of bile which increased in amount over the next 48 hours. ERCP confirmed the block in the CBD. Laparotomy and heptojunostomy was performed, and the patient ultimately recovered. In second patient, this disaster happened because of a congenital anomaly (absent cystic duct). Conversion and choledochojunojustomy was performed.

**Leak from Cholecystohepatic Duct**

This was realized in a patient who returned on the 4th postoperative day with abdominal distension and pain. Ultrasound showed a huge collection under the liver and ultrasound guided drain was placed. As the leakage continued (around 1000 ml of bile daily), laparotomy was performed which revealed a cholecystohepatic duct which was ligated. The patient recovered uneventfully.

**DISCUSSION**

The spectrum of iatrogenic bile duct injuries ranges from clip impingements to complete transection of the common bile duct. We observed almost all of these injuries in our study.

It has been previously suggested that the high rate of biliary injury associated with laparoscopic cholecystectomy is the result of the learning curve. However, other authors have reported it an ongoing problem well beyond the learning period. In our study, all the cases were performed by experienced laparoscopic surgeons who had already performed more than 100 LC, yet the bile duct injuries occurred in 0.92% of cases which indicates that no surgeon is immune from bile duct injuries during LC. Carroll BJ et al also experienced that most of the injuries occurred from surgeons who were out of the learning curve.

In the current study, technical errors were the primary cause of bile duct injuries. In 4 (57.14%) cases, these injuries were the result of misidentification of the anatomy due to inadequate dissection and undue tension, resulting in the tenting of CBD. While in one case (14.28%), injury occurred due to cauterization. Carroll BJ et al observed misidentification of anatomy in 48% cases and cautery injury in 11% of the cases. According to Hunter JG these injuries can be avoided by the use of a 30° angle forward oblique viewing telescope, firm cephalic traction on the fundus and lateral traction on the infundibulum to place the cystic duct perpendicular to the common duct, dissection of the cystic duct where it joins the gallbladder, and routine fluoroscopic cholangiography.

On-table cholangiography (OTC) reduces the chances of bile duct injuries, therefore some authors advocate routine while other selective cholangiography during LC. However, due to lack of facility and expertise we perform LC without OTC. Experience of laparoscopic cholecystectomy in the United States, where OTC is either a routine or selectively performed, showed the incidence of bile duct injury as 0.6%. MacFadyen BV et al observed the incidence of bile duct injury as 0.5%, while Calvete J et al experienced injury rate of 1.3%. In our study, we found the rate of bile duct injuries as 0.92% which is comparable with incidence of centers where OTC is routinely or selectively performed. Archer SB et al in their study also reported better detection rate of bile duct injuries even without doing OTC.

**CONCLUSION**

Laparoscopic cholecystectomy can be performed safely without the use of OTC, provided that pre- and/or postoperative ERCP is available and performed when indicated.
