ABSTRACT

Introduction: To promote oral health among the elderly, we need to know their prosthetic status and prosthetic need. Hence, a survey of prosthetic status and need of elderly inmates of geriatric homes in Hyderabad was done.

Materials and methods: A cross-sectional study was undertaken, and 174 subjects aged 60 years and above were examined of which 103 were male and 71 were female (59.2% males and 40.8% females). The oral examination of the study subjects was carried out using basic oral health surveys, WHO 1997 criteria.

Results: Majority of the subjects, 73 (70.8%) males and 53 (74.6%) females had no prosthesis. Only 4.6% had complete dentures and 21.1% had removable partial dentures and 10.9% had single/multiple bridges. Need for any prosthesis was (83.5%) male and 63 (88.7%) female subjects and nearly 82.8% subjects required one-unit prosthesis.

Conclusion: Dental prosthetic status of people living in geriatric homes is very poor and there is high unmet need for prosthetic care existed among the institutionalized elderly surveyed.

Keywords: Elderly, Geriatric homes, Prosthetic status, Prosthetic needs.

Key messages: A prevention based intervention programs to reduce early tooth loss is recommended and Oral health programs should be specially designed for these special group.

INTRODUCTION

Aging in humans refers to multidimensional process of physical, psychological and social change. With the discoveries in the field of medical science and the improvement of social conditions, the lifespan of an individual has increased. The proportion of older people is growing faster than of any other age group. Because of this, the 21st century may be called as the 'era of population ageing'.

It is estimated that by the year 2025, there will be about 1.2 billion people above the age of 60 years worldwide. It is predicted that the elderly population of India shall be the highest in the world by 2025. Their contribution to the demographic profile is increasing every day. According to the 1991 census, the geriatric population constituted 6.3% of the total Indian population and it is expected to rise to 8.9% in the year 2016 and 21% by the year 2050.

Oral health can be considered as an indicator of general health and quality of life in geriatric patients. Among older people, oral health is generally perceived to be less than physical health. Oral diseases are progressive and cumulative. They become more complex over time. Poor oral health among older people has particularly been seen in a high level of tooth loss, dental caries experience and high prevalence rates of periodontal disease.

Oral healthcare needs of the elderly those living in geriatric homes have been found to be significantly greater. The problems found in them are due to a lack of treatment facilities and information on morbidity profile and are less able financially to afford it.

In this regard, loss of teeth in the elderly is a major concern. This tooth loss can lead to substantial impacts on quality of life. Restoration of missing teeth by appropriate prosthetic treatment is important for the rehabilitation of oral function, chewing ability, esthetic and maintenance of oral and general health.

The dental care among institutionalized elderly has been neglected. Hence the present study was planned to assess prosthetic status and needs among elderly residing in geriatric homes in Hyderabad.
MATERIALS AND METHODS

This cross-sectional survey was conducted in February-March 2012 to determine the prosthetic status and prosthetic need among the institutionalized elderly residing as inmates of Government aided geriatric homes in Hyderabad City, Andhra Pradesh State, India. All inmates aged 60 years and above formed the study population as, in India, this is the criterion for the classification of the elderly.

Before conducting the survey, the investigators visited the geriatric homes to meet the authorities in charge of these centers. Out of eight selected geriatric homes in the city, the authorities of six homes consented to the study.

Inclusion Criteria
All the elderly living in various geriatric homes in Hyderabad city.

Exclusion Criteria
- Study subjects not willing for examination.
- Study subjects with contraindication for examination.
- Nonambulatory/medically/psychologically compromised subjects who could not move out of their room for examination.

From the six geriatric homes, 174 inmates available at that time of study were included in the study population. Inmates were excluded from study as they were severely ill and noncooperative. The aim of the study was explained, their approval was sought and obtained, and the dates for the survey were fixed. Subjects had been informed of the nature of the investigation and had been included in the study after their consent was obtained.

A pretested proforma was used for data collection. It consisted of two parts—the 1st part recorded data on sociodemographic factors (age and gender), while the 2nd part contained a section of the World Health Organization (WHO) Oral Health Assessment Form (1997) to record the prosthetic status and prosthetic need (i.e. denture wearing and need for dentures) of the elderly population.

The investigators were trained and calibrated in recording the proforma and the clinical findings. Standardization and calibration of the recorders was also achieved during the same sessions.

Subjects were examined seated in a chair or stool in open space under natural light, outside the home. The recorder was made to sit close to the examiner so that the instructions and codes could be easily heard and the examiner could see that findings are being recorded correctly.

STATISTICAL ANALYSIS

Data obtained were subjected to the Statistical Package for the Social Sciences (SPSS) Version 17.0. Data comparison was done by applying chi-square tests to find out the statistical significance of the comparisons. Significance level was fixed at $p < 0.05$.

RESULTS

A total of 174 subjects, 103 males (59.1%) and 71 females, (40.8%) aged 60 years and above (age range 60-97 years) formed the study population. The distribution of subjects according to age and gender is given in Table 1.

in 5 (4.8%) male and 3 (4.2%) female subjects only. There was no statistically significant difference between prosthetic status and gender (p > 0.05).

Table 3 shows the number and percentage of subjects with prosthetic needs. Out of 174 residents, 86 (83.5%) male and 63 (88.7%) female subjects required prosthesis. One-unit prosthesis was required most in 39 (37.8%) male and 32 (45%) female subjects, followed by need for multi-unit prosthesis and full removable prosthesis. Full removable dentures were required by 21 (20.4%) male and 14 (19.7%) female subjects. There was no statistically significant difference between prosthetic need and gender (p > 0.05).

**DISCUSSION**

Very few studies have been conducted in India, pertaining to the prosthetic status and needs of people living in geriatric homes. No documented data was available for the institutionalized elderly of Hyderabad city. Therefore, an attempt was made to assess the prosthetic status and need of the residents of geriatric homes in hyderabad city.

In the present study majority of the subjects 73 (70.8%) male and 53 (74.6%) female had no prosthesis. Similar findings were reported by Shenoy and Hegde\(^\text{11}\) in Geriatric Homes in Mangalore where 88% had no prosthesis in upper and lower arch. Soh et al\(^\text{8}\) (1992) reported 78% subjects in long-term care facilities in Singapore were not having any denture. In contradiction studies by Hawkins et al (1998)\(^\text{12}\) reported 80% of subjects were at least one denture and Angelillo et al (1990)\(^\text{13}\) reported 44.3% of the edentulous in both jaws wore complete dentures. Cardoso et al (2011)\(^\text{14}\) reported higher use of upper (79.2%) and lower (37.1%) total prostheses among the elderly people of Manaus city as a result of higher utilization of dental services by them.

In the present study the low proportion of those who had prostheses can be due to the fact that older people under use dental facilities due to lack of awareness, financial constraints and reduced mobility.\(^\text{11}\) The estimation of treatment need is an important stage in oral healthcare planning of elderly. Prosthetic need in the present study for 86 (83.5%) male and 63 (88.7%) female subjects respectively which was in accordance with 76% by Mann J et al (1985)\(^\text{15}\) in Israel and 72% by Shah et al (2004)\(^\text{3}\) in India. Miyazaki et al (1992)\(^\text{16}\) in Japan reported prosthetic need of 36%.

The level of prosthetic need was higher in females 88.7 than males 83.5% but there was no statistically significant difference prosthetic need and gender (p > 0.05). This was in contradiction with a study conducted by Palmqvist (1988)\(^\text{17}\) and Shah (2004)\(^\text{3}\) where prosthetic treatment need for male and female elderly was significantly different and male has higher need for complete denture.

In the current study, the need for single-unit prostheses in 39 (37.8%) male and 32 (45%) female subjects was more than the need for multi-unit prostheses or full prostheses which was in accordance with the studies reported by Goel P et al\(^\text{18}\) and Christensen J.\(^\text{19}\) and in contrast with the study by Shenoy and Hegde (2010)\(^\text{11}\) in Mangalore where the need for multi-unit prostheses was more than the need for one-unit prostheses.

Higher prosthetic need among these institutionalized elderly may attribute to their old age. Factors associated with old age such as reduced salivary flow rate, quality and quantity, lowered immunity and the reduced ability of the body to repair itself may aggravate the process of degradation of the oral tissues.\(^\text{2}\) Although aging alone is not responsible for the deterioration of their oral health, several other factors such as multiple chronic diseases, socio-economic factors, lack of dental facilities and psychological factors such as depression and isolation, because of gradual loss of spouse and friends and feeling of being unwanted by family members, leading to negligence of personnel and oral hygiene and health.

**CONCLUSION**

The findings of this study show that the dental prosthetic status of institutionalized older people living in geriatric homes is very poor and there is high percentage of unfulfilled prosthetic need. A wide gap was seen in between the prosthetic needs and prosthetic status.

Based on the present study findings, following are the recommendations:

- A prevention based intervention program to reduce early tooth loss is recommended for the residents of geriatric homes which includes regular oral health screenings and oral health education programs.
- Oral health programs should be specially designed for these special group and aim at empowerment and self care capacity building of older people and enhance their attitudes, knowledge and oral hygiene practices.
- Oral healthcare facilities should be availed to the residents by taking help from government, non-government agencies and private institutions.
