Successful root canal treatment depends on having comprehensive information regarding the root(s)/canal(s) anatomy. Dentists may have some complication in treatment of third molars because the difficulty in their access, their aberrant occlusal anatomy and different patterns of eruption. The aim of this review was to review and address the number of roots and root canals in third molars, prevalence of confluent canals in third molars, C-shaped canals, dilaceration and fusion in third molars, autotransplantation of third molars and endodontic treatment strategies for third molars.

Keywords: C-shaped canal, Dilaceration, Endodontic treatment, Root canal, Third molar.

INTRODUCTION

Successful root canal treatment depends on having comprehensive information regarding the root(s)/canal(s) anatomy. Careful investigation of the main root canal(s) and extracanal(s) should help the clinician to be aware of the negotiable endodontic space, important parts of the root canal system that may cause treatment difficulties.1

NUMBER OF ROOTS AND ROOT CANALS

Maxillary Third Molars

The number of roots/canals in maxillary third molars varies from one to five. The number of canals in maxillary third molars has been reported from one to six. However, one to three-rooted maxillary third molars are more frequent.2 In a study on Thai maxillary third molars, Alavi et al3 showed that 51% of teeth had three separate roots and 49% had fused or conical roots. Sidow et al4 showed that 15% of maxillary third molars had only one root, 32% had two roots, 45% had three separated roots, whereas 7% had four roots. Pécora et al5 showed that 68% of maxillary third molars had three canals and 34% had four canals. Ng et al6 showed that the prevalence of mesiobuccal roots with two canals in maxillary third molars was 39%. A study showed that 34% of maxillary third molars had four root canals.7 In an in vivo study, Stropko8 showed that 60% of maxillary third molars had three canals and 34% had four canals. Ng et al9 showed that the prevalence of mesiobuccal roots with two canals in maxillary third molars was 39%. A study showed that 34% of maxillary third molars had four root canals.7 In an in vivo study, Stropko8 showed that 60% of maxillary third molars had three canals and 34% had four canals. Ng et al9 showed that the prevalence of mesiobuccal roots with two canals in maxillary third molars was 39%. A study showed that 34% of maxillary third molars had four root canals.7 In an in vivo study, Stropko8 showed that 60% of maxillary third molars had three canals and 34% had four canals.

Mandibular Third Molars

The mandibular third molar presents considerable morphological radicular variations: it can have one or several roots whose form varies; it frequently has two roots, a mesial and a distal one, which often merge, and it usually displays two radicular canals.10-12 Although
the third molars anatomy is unpredictable, restorative, prosthetic, and orthodontic considerations often require endodontic treatment of third molars in order for them to be retained as functional components of the dental arch.\textsuperscript{1,12}

Gulabivala et al\textsuperscript{13} showed that 68% of mandibular third molars had two separate roots, 20% had fused roots and 11% had a single C-shaped root. Sidow et al\textsuperscript{4} concluded that 17% of mandibular third molars had only one root, 77% had two roots, 5% had three roots, and only 1% had four roots. According to Furri et al\textsuperscript{14} 4.6% of mandibular third molars had one canals, 18% had two canals, 72.8% had three canals and 4.6% had four canals.

A study on an Iranian population showed that 21% of third molars had one root, 73% had two roots and 5% had three roots.\textsuperscript{15} Plotino\textsuperscript{16} presented a mandibular third molar with three separate mesial roots.\textsuperscript{15} Cosić et al\textsuperscript{9} showed that 56% of lower third molars had one root and had two root canals in 90% of cases.

Confluent Root Canals in Third Molars

According to the Weine classification of the root canal system, there are four types of the root canal. Among these, type two comprises two separate canals leaving the pulp chamber but merging short of the apex to form only one canal. The other name of type two canals of the Weine classification is confluent canals.\textsuperscript{17}

Furri et al\textsuperscript{14} did not report any confluent canals in the mandibular third molars. Pineda and Kuttler\textsuperscript{12} reported 20.6% of confluent canals in the mesiobuccal roots of the maxillary third molars. Pecora et al\textsuperscript{12} reported 18% confluent canals in the mesiobuccal roots of the maxillary third molars. Pineda and Kuttler\textsuperscript{12} reported confluent canals in the 18 and 4% in the mesial and distal roots of the mandibular third molars, respectively. Another study showed that 36% of the mesial roots of mandibular third molars had confluent canals.\textsuperscript{14}

Dilacerated Roots in Third Molars

Dilaceration is defined as a deviation in the linear relationship of a crown to the related root. The mechanical trauma to the primary tooth is the most important cause of dilaceration in succedaneous tooth.\textsuperscript{18}

Hamasha et al\textsuperscript{19} reported that the incidence of dilacerated roots was 1.33% for maxillary third molars and 19.21% for mandibular third molars. Kannan et al\textsuperscript{20} reported a four-rooted maxillary third molar with dilacerated roots. In an \textit{in vivo} radiographic study using periapical and panoramic radiographs, Malcic et al\textsuperscript{21} showed that the incidence of dilaceration was 8.1 and 8.46% for maxillary third molars using periapical and panoramic radiographs, respectively and 24.1 and 30.92% for mandibular third molars using periapical and panoramic radiographs, respectively. Using periapical radiographs, Udoye and Jafarzadeh\textsuperscript{22} showed that the incidence of dilacerations in maxillary third molars was 3.7% and in mandibular third molars was 3.3%. In another study in a Turkish population, the incidence of dilaceration in maxillary and mandibular third molars was 7.4 and 12.8%, respectively.\textsuperscript{23} A study in an Iranian population showed that the incidence of dilacerated roots in mandibular third molars was 8% (Table 1).\textsuperscript{15}

C-shaped Canals

The pulp chamber of a C-shaped canal has a long ribbon-shaped isthmus with at least 180° arc. Below the orifice, the root anatomy has a wide range of variations.\textsuperscript{24}

In an \textit{in vitro} study using clearing method, Sidow et al\textsuperscript{4} showed that the incidence of C-shaped canals in maxillary third molars (two-rooted) was 7/150 and in mandibular third molars was 3/150 for both single-rooted and two-rooted teeth. According to Gulabivala et al\textsuperscript{13} the incidence of C-shape anatomy in mandibular third molars of Thai population was 11% \textit{in vitro}. A study in an Iranian population showed that the incidence of C-shaped canals in mandibular third molars was 3.5% (Table 2).\textsuperscript{15}

FUSION

Fusion is a developmental anomaly refers to the union of two normal distinct tooth germs or a normal germ with a supernumerary one. The etiology of fusion is still unclear, but is likely, in part, related to the physical forces

The Journal of Contemporary Dental Practice, April 2015;16(4):310-313
produced by the close contact between two developing teeth. A genetic predisposition has been reported, and racial differences in incidence are evident.\textsuperscript{25,26}

Hemmig\textsuperscript{26} reported a mandibular third molar fused to a distomolar. Hou and Tsai\textsuperscript{27} reported a maxillary third molar fused to a distomolar. Shteyer\textsuperscript{28} reported fusion of a mandibular third molar with a distomolar. Morris\textsuperscript{29} reported fusion of mandibular third molar with a supernumerary fourth molar. Fusion of a mandibular third molar with a mandibular second molar has also been reported.\textsuperscript{30} Turell and Zmener\textsuperscript{31} reported both left and right mandibular third molars fused to distomolars. Conte et al\textsuperscript{32} reported a fusion between a mandibular third molar and a supernumerary tooth (fused to its distal surface).

**Treatment Strategies for Third Molars**

As the third molar tooth in the most posterior location the access to it is restricted and so easier handling of treatment procedures would be provided by using special guidelines. Using contra-angle hand-piece with a small head improves the access to third molars.

Furthermore, using short files (21 mm) and short gates-glidden drills will also enhances accessibility of root canals of third molar teeth. Despite the fact that hand spreaders produce more stress during compaction of gutta-percha, due to the limited access during endodontic treatment of third molars, hand spreaders seem to be more appropriate for lateral compaction technique compared to finger spreaders.

**An Important Note during Access Cavity Preparation**

Maxillary third molar usually has a distally tilt whereas the mandibular third molar has a mesially tilt. For preparation of the access cavity in mandibular ones, the handpiece should be placed at the tooth long axis for avoiding mesial perforation.

**Autogenous Transplantation**

Autotransplantation is defined as the transplantation of a tooth, either with complete or incomplete root formation, from one site to another in the same individual.\textsuperscript{33} According to Bauss et al\textsuperscript{34} as well as Reich,\textsuperscript{35} if autotransplantation is performed accurately, the success rate can reach over 90%.

Third molars can be considered as appropriate candidates to replace hopeless or missed first and second molars, as well as premolars.\textsuperscript{36} To avoid the undesirable consequences following pulp death and root resorption, root canal treatment is usually recommended, in mature teeth, 3 to 4 weeks after autotransplantation.\textsuperscript{37,38} It was recommended that the pulp of teeth with closed apices be extirpated 7 to 14 days after transplantation; otherwise the necrotic pulp and subsequent infection may result in inflammatory resorption and decrease the survival time of the autografts.\textsuperscript{39}

The prognosis of autotransplantation is favorable as long as the case is selected precisely, the surgical procedure is performed as atraumatic as possible and the patient is able to follow the postoperative instructions and maintain good oral hygiene measures.\textsuperscript{39}
